Classical first-order logic enjoys the Fraïssé definability property. According to this property, a concept is definable if, and only if, its satisfiability is preserved under partial isomorphisms. This metatheoretical property is important since it provides precise limits on classical definability. It is therefore of interest to investigate whether a corresponding property holds in non-classical contexts as well. In this presentation, we show that a broad family of logics of formal inconsistency fails to satisfy the Fraïssé definability property. In these logics, the preservation of satisfiability under partial isomorphisms often does not entail first-order definability. To show this, we contribute an investigation on the model theory of logics of formal inconsistency and develop new techniques on the construction of models for these paraconsistent logics.
